Fall 2024 ECE 355

Assignment 5 Due November 20, 23:59

NOTE: Late submissions will not be accepted. Please submit a single PDF file with your answers via the **ECE 355 Brightspace** webpage.

1. [5 points] Consider the code portion of the <u>matrix-vector product</u> computation as shown below: (double) 128x128 matrix A is multiplied by (double) 128x1 vector X, producing (double) 128x1 result Y (initially all 0's).

```
for (i = 0; i < 128; i++) {
    for (j = 0; j < 128; j++) {
        Y[i] = Y[i] + A[i][j]*X[j];
    }
}</pre>
```

Storing **X**, **Y**, and **A** (each double array element is 8 bytes in size) requires 128*8 + 128*8 + 128*128*8 = **130 KB** of memory. If the cache (assume fully associative) is smaller than 130 KB, the above code will cause many misses, considerably slowing down the program execution. Alternatively, one can perform blocked computation: partition **A** into smaller blocks and perform the product computation block-by-block. If our data blocks can fit into the cache, such blocked computation may significantly outperform the original code.

Rewrite the code fragment above using <u>blocked computation</u> and letting matrix **A**'s blocks be of size **64x64** (i.e., 4 blocks total). Assuming that such blocking yields the best performance, what can you say about the size of the cache?

2. [10 points] Consider a <u>C code</u> fragment below, processing some <u>matrix</u> float x[n][n] (stored row by row, i.e., in the row-major order), where n = 512:

```
float y, neg = 0;
for (i = 0; i < N; i++) {
    for (j = 0; j < N; j++) {
        if (X[i][j] < 0) neg++; /* count negative elements */
    }
}
y = neg/(N*N);
for (i = 0; i < N; i++) {
    X[i][i] = X[i][i] + y; /* add to diagonal */
}</pre>
```

Determine the x-related <u>page fault rate</u> in the following <u>two cases</u>: 1) the main memory uses **1-KB** paging with <u>4 pages</u> allocated for x, and 2) the main memory uses **2-KB** paging with <u>2 pages</u> allocated for x. Initially, no part of x is in the main memory. **Note:** f(x) = f(x)

3. [10 points] Consider a <u>C code</u> fragment below, processing some positive <u>matrix</u> unsigned int X[N][N] (stored row by row, i.e., in the row-major order), where N = 1024:

Determine the \mathbf{x} -related <u>page fault rate</u> in the following <u>two cases</u>: 1) the main memory uses **1-KB** paging with <u>4 pages</u> allocated for \mathbf{x} , and 2) the main memory uses **4-KB** paging with <u>1 page</u> allocated for \mathbf{x} . Initially, no part of \mathbf{x} is in the main memory. **Note:** <u>unsigned int = 4 bytes</u>.
